1 SCOPE OF THE EAD

1.1 Description of the construction product

The construction product is a joint sealing tape made of a flexible impregnated pre-compressed polyurethane foam hereinafter referred as sealing tape. This EAD covers only products of reaction to fire class E or F.

The sealing tape consists of
- precompressed polyurethane foam
- sealing mass

The joint sealing tapes show different dimensions as to width and thickness with a different performance depending on the dimensions and movement capacity of the joint of the construction. For installation purposes they are delivered in various lengths on spools, pre-compressed and with laminated single-sided self-adhesive foil.

The product is not covered by a harmonised European standard (hEN).

Concerning product packaging, transport, storage, maintenance, replacement and repair it is the responsibility of the manufacturer to undertake the appropriate measures and to advise his clients on the transport, storage, maintenance, replacement and repair of the product as he considers necessary.

It is assumed that the product will be installed according to the manufacturer’s instructions or (in absence of such instructions) according to the usual practice of the building professionals.

Relevant manufacturer’s stipulations having influence on the performance of the product covered by this European Assessment Document shall be considered for the determination of the performance and detailed in the ETA.

1.2 Information on the intended use(s) of the construction product

1.2.1 Intended use(s)

The joint sealing tape is used to seal joints around non-metallic windows and joints in non-metallic building façades to resist penetration of water and air.

The function of sealing tapes remains safe up to severe low temperatures of $\sim 20^\circ$C or even lower temperature (-25 °C, -30 °C or $\sim 40^\circ$C), as indicated by the manufacturer. This shall be stated in the ETA.

The single-sided self-adhesive foil serves as installation assistance.

The dimensioning of the product for the operating rate of joint width shall be given in the ETA. The highest and lowest value includes possible movements of the joint width due to influence of temperature.

The opened roles have to be closed immediately after finishing work, so that the tape cannot expand.

1.2.2 Working life/Durability

The assessment methods included or referred to in this EAD have been written based on the manufacturer’s request to take into account a working life of the sealing tape for the intended use of 10 years when installed in the works provided that the sealing tape is subject to appropriate installation (see 1.1). These provisions are based upon the current state of the art and the available knowledge and experience.
When assessing the product, the intended use as foreseen by the manufacturer shall be taken into account. The real working life may be, in normal use conditions, considerably longer without major degradation affecting the basic requirements for works.

The indications given as to the working life of the construction product cannot be interpreted as a guarantee neither given by the product manufacturer or his representative nor by EOTA when drafting this EAD nor by the Technical Assessment Body issuing an ETA based on this EAD, but are regarded only as a means for expressing the expected economically reasonable working life of the product.

1.3 Specific terms used in this EAD

**Geometry of the joint and the sealing tape**

![Diagram](image)

- \( t_F \) Width of the sealing tape = minimum depth of the joint
- \( b_0 \) Thickness of the uncompressed sealing tape
- \( \text{b}_{\text{Lmin}} \) Minimum thickness of the compressed sealing tape at state of delivery
- \( \text{b}_N \) Nominal width of the joint according to declaration of the manufacturer:
  \[ \text{b}_{\text{min}} + (\text{b}_N \times 25 \%) \leq \text{b}_N \leq \text{b}_{\text{max}} - (\text{b}_N \times 25 \%) \]
- \( \text{b}_{\text{min}} \) Minimal joint width [mm]
- \( \text{b}_{\text{max}} \) Maximum joint width [mm]
- \( b \) Joint width during installation: \( \text{b}_{\text{min}} \leq b \leq \text{b}_{\text{max}} \)
- \( a \) Degree of compression, \( a = \frac{b}{b_0} \times 100 \% \) (100 % is the uncompressed sealing tape)
- \( \text{k}^* \) Movement capacity \( \text{k}^* = \text{b}_{\text{max}} - \text{b}_{\text{min}} \).

---

1 The real working life of a product incorporated in a specific works depends on the environmental conditions to which that works is subject, as well as on the particular conditions of the design, execution, use and maintenance of that works. Therefore, it cannot be excluded that in certain cases the real working life of the product may also be shorter than the working life referred to above.
2 ESSENTIAL CHARACTERISTICS AND RELEVANT ASSESSMENT METHODS AND CRITERIA

2.1 Essential characteristics of the product

Table 1 shows how the performance of the joint sealing tape is assessed in relation to the essential characteristics.

2.2 Methods and criteria for assessing the performance of the product in relation to essential characteristics of the product

2.2.1 Reaction to fire

The joint sealing tape shall be tested, using the test method(s) relevant for the corresponding reaction to fire class according to EN 13501-1. The joint sealing tape shall be classified according to Commission Delegated Regulation (EU) No 2016/364 in connection with EN 13501-1.

2.2.2 Driving rain tightness

The driving rain tightness of the joints and the braces of the joint shall be determined according to EN 1027 method 1A for the highest degree of compression $a_{\text{test}} = (b_{\text{test}}/b_0) \times 100\%$, specified by the manufacturer oriented at $b_{\max}$ and the minimum width $t_f$ of the sealing tape.

A test specimen shall be made with three longitudinal joints for the test. To do so, the sealing tape shall be installed joint width depending on $a_{\text{test}}$ between 1.1 m long rectangular tubes of aluminium according to EN 755-1 which are mounted parallel to the width of the joint $b_A$ (see Annex A, Figure 1). For braces of the joint see Annex A, Figure 2.

The driving rain tightness of the joints and the braces of the joint shall be classified according to EN 12208. With the test result and under consideration of the aging influence all sealing tapes with a lower degree of compression $a$ (see calculation according Annex B) and with a higher width $t_f$ are covered. The minimum joint width $b_{\min}$ cannot be smaller than $b_{\text{Lmin}}$.

2.2.3 Water vapour diffusion resistance

The water vapour diffusion resistance shall be determined according to EN ISO 12572 with test conditions in sentence C.

The joint width of the test specimen shall be the nominal joint width $b_N$.

The water vapour diffusion factor $\mu$ shall be given in the ETA.

2.2.4 Air permeability

The air permeability shall be determined according to EN 1026. The joint width of the test specimen for the highest degree of compression $a_{\text{test}} = (b_{\text{test}}/b_0) \times 100\%$, specified by the manufacturer oriented at $b_{\max}$ and the minimum width $t_f$ of the sealing tape. The joint permeability coefficient $a \left[ m^3/(h \cdot m \cdot (daPa)^{2/3}) \right]$ shall be determined according to EN 12114.

The air permeability shall be classified according to EN 12207. The joint permeability coefficient shall be given in the ETA.

With the test result and under consideration of the aging influence all sealing tapes with a lower degree of compression (see calculation according Annex B) and with a higher width $t_f$ are covered. The minimum joint width $b_{\min}$ cannot be smaller than $b_{\text{Lmin}}$.

2.2.5 Resistance to change in temperatures

For testing the resistance to change in temperature the sealing tape shall be built in for the lowest degree of compression $a_{\text{test}} = (b_{\text{test}}/b_0) \times 100\%$, specified by the manufacturer oriented at $b_{\min}$ between rectangular tubes of 0.2 m, made of aluminium according to EN 755-1, which are mounted parallel to the width of the joint (see Annex A, Figure 3). Between the sealing tape and one of the rectangular tubes a separating foil shall be arranged which shall prevent the gluing of tape and tube. After pre-storing for 7 days at standard climate one test specimen shall be subject to three times the following cycle of storing:

a) exposure in an oven at $50 \pm 2 \, ^{\circ}C$ for 22 h,
followed by 2 h in an oven at 80 ± 2 °C.
This process shall be repeated twice.

b) immersion in distilled water at 23 ± 2 °C for 1 day

c) exposure in a freezer at -20 ± 2 °C or lower temperature as indicated by the manufacturer
(-25 °C, -30 °C or −40 °C) for 3 days

Subsequently the test specimen shall be stored one more day at standard climate.

After this procedure the test specimen is tested for water tightness according the following procedure:

The water tightness shall be tested with a head of water of 60 mm in a test tube at standard climate. There shall be no sign of water after 3 min on the backside of the test specimen.

Then the contact surfaces shall be inspected for discoloring and drifting of impregnating agent and the remaining compression deformation of the sealing tape shall be determined after 6 h in accordance with EN ISO 1856.

The joint sealing tape shall remain watertight. If the product fails this test, the intended use shall be limited for the sealing only of joints without standing water (e.g. vertical joints).

No discoloration on the contact surfaces due to the impregnating agent having drifted and are visible at a width of 1 mm at the most next to the sealing tape.

The re-deformation shall at least amount to the nominal joint width + 50 % (≥1,5bₙ).

2.2.6 Resistance to the effects of actions of UV radiation in the presence of moisture

Testing of the resistance to the effects of actions of light and moisture is to be done according to EN ISO 4892-2. The test procedure is specified as follows:

Testing shall be performed on a joint sealing tape of a nominal joint width (see Figure 4). Twin determinations shall be performed. For that purpose two sealing tapes are installed in the holding device. The holding device for the specimen consists of a sample holder belonging to the Xenon test apparatus (EN ISO 4892-2) intended for weathering of rectangular samples to be converted for lateral weathering of tapes made of plastic foams.

For that purpose a slot of 16 mm width is centered at the longitudinal sides of which angles were set on both sides so that the depth of the sealing tape amounts to 30 mm. Two angles are equipped with 6 adjusting screws each. Two samples of the sealing tape of a length of 90 mm and a width of 30 mm shall be glued with the self-adhesive side to the sheet metal supports, dimensions 90 mm x 30 mm, thickness of 1 mm. Using the adjusting screws the nominal width of the joint shall be adjusted to 12 mm, after which they shall be fixed to the sample holder. The sample holder with the built-in samples shall be conditioned at standard atmosphere for at least 24 h.

Then the test specimen shall be hung up in a Xenon test apparatus and be weathered for a total of 3 months in the test chamber at a light/dark alternation with cycles according to EN ISO 4892-2, Table 3, Method A, cycle 1. The sum of the radiation during this period per test area amounts to 240 MWs/m² ± 5 %. Afterwards the samples shall be stored in the drying oven at 50 °C for 1 h and a further 24 h at standard atmosphere. After opening the sample holder, the condition of the sealing tape and the contact surfaces shall be evaluated and the remaining compression deformation shall be measured after 6 h in accordance with EN ISO 1856.

The joint sealing tape shall remain watertight. There shall be no visible leakage of the impregnating agent. The re-deformation of the sealing tape 6 h after opening the test specimen shall amount to at least the maximum joint width (≥ bₘₐₓ).
The Technical Assessment Body shall evaluate the influence of ageing of the remaining degree of compression for judging the range of joint width for a given set of sealing tapes that the sealing of joints remains watertight at driving rain for all joint width (see Annex B).

2.2.7 Resistance to heat ageing

The remaining compression deformation of a joint tape for the lowest degree of compression \( a = (b_{\text{testo}}/b_0) \times 100 \% \), specified by the manufacturer oriented at \( b_{\text{min}} \) according to EN ISO 1856 shall be determined after heat ageing of 72 h at 70 °C ± 2 °C. The sealing tape shall be compressed between rectangular tubes of 0,2 m, made of aluminium according to EN 755-1, which are mounted parallel to the width of the joint. Measuring the re-deformation shall be performed after a subsequent storing of 24 h at standard atmosphere.

After the treatment and after de-compression the joint sealing tape shall reach at least the nominal joint width + 50 % (≥ 1,5 \( b_0 \)).

The Technical Assessment Body shall evaluate the influence of ageing of the remaining degree of compression for judging the range of joint width for a given set of sealing tapes that the sealing of joints remains watertight at driving rain for all joint width. (see Annex B)

2.2.8 Compatibility with adjoining construction materials

The compatibility of the sealing tape with concrete, facing brick, calcareous sandstone, white PVC, and pinewood with and without coating shall be tested. For that purpose the sealing tape shall be built in between two approx. 0.2 m long pieces each of the construction material which are mounted at a nominal joint distance of 12 mm. The test specimen shall be tightly wrapped up with aluminium foil and stored in the oven at 80 ± 2 °C for 14 days followed by an assessment of the contact areas.

Compatibility of the joint sealing tape with concrete, facing brick, calcareous sandstone, pinewood with or without coating as well as with white PVC is ensured where no alternations on the contact surfaces develop affecting the functions and discoloration on the contact surfaces due to the impregnating agent having drifted and are visible at a width of 1 mm at the most next to the sealing tape.
3 ASSESSMENT AND VERIFICATION OF CONSTANCY OF PERFORMANCE

3.1 System(s) of assessment and verification of constancy of performance to be applied

For the products covered by this EAD the applicable European legal act is: Decision 98/436/EC.

The system is 4 for any use except for uses subject to regulations on external fire performance or on dangerous substances.

For uses subject to regulations on external fire performance the applicable AVCP systems are 3 or 4 depending on the conditions defined in the said Decision.

For uses subject to regulations on dangerous substances the applicable AVCP system is 3.

3.2 Tasks of the manufacturer

The cornerstones of the actions to be undertaken by the manufacturer of the product in the procedure of assessment and verification of constancy of performance are laid down in Table 3.

ANNEX 2: EXAMPLE OF THE VERIFICATION OF AGING INFLUENCE FOR DIFFERENT DIMENSIONS OF JOINT SEALING TAPES

According to clause 1.2.2.2 of the EAD Design and dimensioning the sealing tapes shall be chosen such that at given maximum joint width related to the allowable degree of compression which had been derived from the attained driving rain tightness and the air permeability under consideration of impact of ageing will not fall short.

This is verified according to the following assessment procedure:

In Table B.1 the manufacturers declaration of the sealing tapes for permissible joint width due to temperature induced movements of joints are given. In relation to the thickness of the noncompressed sealing tape $b_0$ the degree of compression is given for the highest permissible value of the joint width. That leads to a maximum degree of compression of $\varepsilon_{\text{max}} = 33.8 \%$.

To verify that the joint sealing remain water tight at the maximum degree of compression the driving rain test was carried out with a sealing tape which noncompressed height was 60 mm, which gives higher degree of compression than normally will be used in practice.

Table B.2 gives the results of tapes at that degree of compression

To have a sufficient security that the contact stress of the tape to the joint shoulders will be reached also under ageing conditions the proved maximum degree of compression of $a_{\text{test}} = 40\%$ will be reduced with the relation of the heat ageing influence to the compression behaviour.

The test of heat ageing and of change in temperature give the lowest decompression up to 45,1 mm for the uncompressed height of the tape of 60 mm i.e. $a_{\text{ageing}} = 75,2\%$ by tape N° 1 and the lowest decompression up to 53,2 mm for the noncompressed height of the tape of 60 mm i.e. $a_{\text{ageing}} = 88,7\%$ by tape N° 2.

In this case a linear modification is assumed of the influence of ageing to the remaining degree of compression (see sketch and equation).

Equation for determining the maximum allowable degree of compression:

$$a_{\text{max}} = \left(\frac{a_{\text{ageing}} - a_{\text{testo}}}{a_{\text{o}} - a_{\text{testo}}}\right) a_{\text{testo}} + a_{\text{testo}}$$

- $a_{\text{o}}$ sealing tape without degree of compression: 100 %
- $a_{\text{testo}}$ sealing tape starting degree of compression for the driving rain test (see ch. 2.2.8, lowest degree of compression, related to $b_{\text{min}}$): in this example 20 % in this case 20 %
- $a_{\text{ageing}}$ sealing tape with remaining degree of compression after ageing (see ch. 2.2.8 degree of compression after de-compression): in this example 88,7 %
- $a_{\text{test}}$ sealing tape with reached degree of compression at driving rain test (see ch. 2.2.3, highest degree of compression, related to $b_{\text{max}}$): in this example 40,0 %
- $a_{\text{max}}$ maximum allowable degree of compression of the sealing tape as a result of the equation is in this example 33,8 % for tape N° 1 and 37,2 % for tape N° 2

Table B.3 shows the degree of compression of the joint sealing tape.

</table>
This confirms that the types of joint sealing tapes indicated by the manufacturer are covered by the tests and that the testing procedure was in accordance with the EAD and did not influence the classification according to EN 12208 in class 9a (test pressure ≥ 600 Pa tape N° 1) or the classification according to EN 12208 in class 7a (test pressure ≥ 300 Pa tape N° 2). In this case the classification of the air permeability according to EN 12207 is not influenced negatively for both tapes.

The degree of compression of the sealing tapes must be lower than the maximum allowable degree of compression \( a_{\text{max}} = 37.2\% \) and \( a_{\text{max}} = 33.8\% \).

As it is shown in table B3 the degree of compression of the joint sealing tape is in any case lower than these values.
