Annex B Method for testing of elevator lifting device .................................................... 11
1 SCOPE OF THE EAD

1.1 Description of the construction product

The EAD covers the assessment of pre-installed elevator lifting device embedded in normal weight concrete according to EN 206-1 and anchored by bonding and mechanical interlock.

The product consists of a threaded steel rod, a chain link made of steel and a plastic housing. The threaded rod is bent about 20° at the middle. The product is assembled as shown in Figure 1 of Annex A. The plastic housing is equipped with a plastic cover that is removed when the product is embedded and the chain link is going to be used. The plastic housing is intended to facilitate proper embedment in the concrete and is not meant to carry any load.

The product is not covered by a harmonised European standard (hEN).

Concerning product packaging, transport, storage, maintenance, replacement and repair it is the responsibility of the manufacturer to undertake the appropriate measures and to advise his clients on the transport, storage, maintenance, replacement and repair of the product as he considers necessary.

It is assumed that the product will be installed according to the manufacturer’s instructions or (in absence of such instructions) according to the usual practice of the building professionals.

Relevant manufacturer’s stipulations having influence on the performance of the product covered by this European Assessment Document shall be considered for the determination of the performance and detailed in the ETA.

The concrete slab is designed according to EN 1992-1-1. The load from the lifting device can be designed as a point load acting on the slab. The design capacity of the lifting device is the minimum of steel capacity and concrete capacity. Provisions for the design are given in the ETA with respect to:

- Minimum surface reinforcement present around the lifting device.
- Minimum slab thickness.
- Minimum/maximum concrete strength.
- Minimum spacing distance.
- Minimum edge distance.

1.2 Information on the intended use(s) of the construction product

1.2.1 Intended use(s)

The product is intended to be cast into the roof of an elevator shaft, to transfer the load from the elevator car to the concrete slab during the elevator installation, see Figure 2 of Annex A. It can be used for precast and cast in situ slabs. Typically, three elevator lifting devices are embedded in each slab.

A wire, or similar, can be attached to the chain link when the product is fully cast in and the plastic cover has been removed, see Figure 3 of Annex A.

One lifting device takes the full load of the elevator car. The lifting device is intended for mainly tensile loads where only small angular deviations are allowed. The lifting device is intended to carry mainly static or quasi-static loads.

Depending on the materials used for the elevator lifting device the following categories of durability are envisaged:

- under dry internal conditions;
- under external atmospheric conditions, in industrial atmosphere and in marine environment.
1.2.2 Working life/Durability

The assessment methods included or referred to in this EAD have been written based on the manufacturer's request to take into account a working life of the elevator lifting device for the intended use of 50 years when installed in the works. These provisions are based upon the current state of the art and the available knowledge and experience.

When assessing the product the intended use as foreseen by the manufacturer shall be taken into account. The real working life may be, in normal use conditions, considerably longer without major degradation affecting the basic requirements for works.

The indications given as to the working life of the construction product cannot be interpreted as a guarantee neither given by the product manufacturer or his representative nor by EOTA when drafting this EAD nor by the Technical Assessment Body issuing an ETA based on this EAD, but are regarded only as a means for expressing the expected economically reasonable working life of the product.

1.3 Specific terms used in this EAD

The specific terms used in this EAD are given in Annex A.

2 ESSENTIAL CHARACTERISTICS AND RELEVANT ASSESSMENT METHODS AND CRITERIA

2.1 Essential characteristics of the product

Table 1 shows how the performance of the elevator lifting device is assessed in relation to the essential characteristics.

</tbody>
</table>

The real working life of a product incorporated in a specific works depends on the environmental conditions to which that works is subject, as well as on the particular conditions of the design, execution, use and maintenance of that works. Therefore, it cannot be excluded that in certain cases the real working life of the product may also be shorter than referred to above.
2.2 Methods and criteria for assessing the performance of the product in relation to essential characteristics of the product

2.2.1 Reaction to fire

The elevator lifting device shall be tested, using the test method(s) relevant for the corresponding reaction to fire class, in order to be classified according to EN 13501-1.

The metallic parts is considered to satisfy the requirements for performance class A1 of the characteristic reaction to fire in accordance with the EC Decision 96/603/EC (as amended) without the need for testing on the basis of it fulfilling the conditions set out in that Decision and its intended use being covered by that Decision.

2.2.2 Load bearing capacity

The load bearing capacity of the elevator lifting device shall be determined by structural testing or calculation. The load bearing capacity is defined as the ultimate failure load of the system (concrete failure or steel failure).

Structural calculations shall be in accordance with relevant Eurocodes. Structural testing shall be based on European Standards, and be accompanied by structural calculations.

Test method according to Annex B.

The evaluation of the test result should follow the procedures given in EN 1990, Annex D. The characteristic capacity is defined as the 5 %-fractile of the ultimate loads measured in a test series at a confidence level of 75 %. In general, a normal distribution and an unknown standard deviation of the population should be assumed.

The design capacity of the lifting device is calculated using relevant safety factor for the situation where the product is used.

2.2.3 Durability (Corrosion resistance)

The durability (corrosion resistance) depends on the chosen materials/coatings and the environmental conditions at the place of use.

The corrosion resistance that ensures the suitability and the bearing behaviour of metal parts of the elevator lifting device shall be shown. No special test conditions can be given in this EAD for checking the durability of any coating because they depend on the type of coating.

The assessment/testing required with respect to corrosion resistance will depend on the specification of the elevator lifting device in relation to its use.

Assessment of the durability of any coating is based on the type of coating and the intended conditions of use (i.e. dry internal or external conditions).
3 ASSESSMENT AND VERIFICATION OF CONSTANCY OF PERFORMANCE

3.1 System(s) of assessment and verification of constancy of performance to be applied

For the products covered by this EAD the applicable European legal act is: Decision 1997/161/EC.

The system is: 2+

3.2 Tasks of the manufacturer

The cornerstones of the actions to be undertaken by the manufacturer of the product in the procedure of assessment and verification of constancy of performance are laid down in Table 2.

ANNEX B  METHOD FOR TESTING OF ELEVATOR LIFTING DEVICE

Test specimen

The size of the surrounding concrete for the manufactured test specimens shall be adjusted so that the failure of the actual elevator lifting device can occur without being affected by the test rig. This can be considered satisfied if the length and width measurements are at least as large as the actual elevator lifting device plus 4 times the concrete thickness in each direction.

The thickness of the concrete shall be the specified minimum allowable thickness. In cases where reinforcement is specified around the elevator lifting device, this should also be included in the manufactured test specimen. The selected concrete quality in the casting of the test object shall be the lowest recommended quality and optimized so that the strength is as close as possible to the characteristic value of the concrete strength class.

Testing shall be performed on at least three specimens.

At the same time as the test specimens are cast, three additional cubes shall be cast and be stored under the same conditions as the test specimens.

Testing

The testing should normally be performed about 28 days after production.

During the testing, any connection between the test rig and the specimen shall be placed outside of the area where potential failure can occur. The connections are preferably placed at a distance of at least 1 x the concrete thickness from the actual elevator lifting device.

The test specimen is loaded with a continuously increasing load so that the failure is achieved after about two minutes. The elevator lifting device's deformation is measured relative to the concrete surface. A test of the concretes compressive strength at the time of testing shall also be performed.

Results and Evaluation

The report presents the maximum achieved load as well as a graph of the force-deformation relationship. The report shall even include a description of the test object as well as the compressive strength of the concrete at the time of the test. If the tests resulted in a fracture of the concrete, the failure load shall be adjusted to take into account any overcapacity of the tested concrete compared with the nominal concrete.

The elevator lifting device's steel grade shall also be reported. Information for this item can be obtained either by reviewing an inspection certificate 3.1 according to EN 10204 from the manufacturer or by performing tensile testing of rods from the same batch as the tested item.
