1 SCOPE OF THE EAD

1.1 Description of the construction product

The product is a mechanical fastener (cartridge fired pin / powder actuated fastener)\(^1\) made of steel. The fastener comprises of a pin with a minimum diameter of 3.7 mm which is normally assembled with one or two washers. The washers serve to guide the fastener while it is being driven into the base material. The washers also serve to improve the bearing area. A special fastening tool is used in order to install the fastener. The driving force of the fastening tool is provided by the power load of the cartridge. The application limit depends on the strength and thickness of the base material.

Fastener, fastening tool and cartridge are shown in Annex 1.

The fastener and the corresponding connections are subject to tension and/or shear forces (see Annex 2). Typical failure modes of connections made with cartridge fired pins are shown in Annex 3.

The assessment of the load-bearing capacity of the fastener and the corresponding connections are part of this EAD. The fastening tool (incl. cartridge) is an integral part of this assessment with regards to its effect on the capacity of the connection.

The product is not covered by a harmonised European standard (hEN).

Concerning product packaging, transport, storage, maintenance, replacement and repair it is the responsibility of the manufacturer to undertake the appropriate measures and to advise his clients on the transport, storage, maintenance, replacement and repair of the product as he considers necessary.

It is assumed that the product will be installed according to the manufacturer’s instructions or (in absence of such instructions) according to the usual practice of the building professionals.

Relevant manufacturer’s stipulations having influence on the performance of the product covered by this European Assessment Document shall be considered for the determination of the performance and detailed in the ETA

1.2 Information on the intended use(s) of the construction product

1.2.1 Intended use

The fastener is intended to be used for fastening steel sheeting with a tensile strength ≥ 330 N/mm\(^2\) and a thickness \(t_I ≥ 0.63\) mm to steel members (base material) with a tensile strength ≥ 360 N/mm\(^2\) and a thickness \(t_{II} ≥ 3.0\) mm, provided the relevant application limits are taken into account. The sheeting can either be used as cladding or as load bearing wall and roof element. The fastener can also be used for the fastening of other thin gauge steel members. The intended use only comprises fasteners and connections which are not directly exposed to external weather conditions. Furthermore, the intended use comprises connections with predominantly static loads (e.g. wind loads, dead loads).

1.2.2 Working life/Durability

The assessment methods included or referred to in this EAD have been written based on the manufacturer’s request to take into account a working life of the cartridge fired pin for the intended use of 25 years when installed in the works (provided that the cartridge fired pin is subject to appropriate installation). These provisions are based upon the current state of the art and the available knowledge and experience.

\(^1\) Both terms (cartridge fired pin and powder actuated fastener) are commonly used
When assessing the product, the intended use as foreseen by the manufacturer shall be taken into account. The real working life may be, in normal use conditions, considerably longer without major degradation affecting the basic requirements for works.

The indications given as to the working life of the construction product cannot be interpreted as a guarantee neither given by the product manufacturer or his representative nor by EOTA when drafting this EAD nor by the Technical Assessment Body issuing an ETA based on this EAD, but are regarded only as a means for expressing the expected economically reasonable working life of the product.

## 2 ESSENTIAL CHARACTERISTICS AND RELEVANT ASSESSMENT METHODS AND CRITERIA

### 2.1 Essential characteristics of the product

Table 1 shows how the performance of the cartridge fired pin is assessed in relation to the essential characteristics.

The real working life of a product incorporated in a specific works depends on the environmental conditions to which that works is subject, as well as on the particular conditions of the design, execution, use and maintenance of that works. Therefore, it cannot be excluded that in certain cases the real working life of the product may also be shorter than the working life referred to above.

### 2.2 Methods and criteria for assessing the performance of the product in relation to essential characteristics of the product

#### 2.2.1 Tension resistance of connection

The possible failure modes of a connection of steel components (component $t_I$ and component $t_{II}$) with a cartridge fired pin under tensile load are:

- Pull-through failure of component $t_I$ (sheeting)
- Pull-out failure (pin pull-out of base material component $t_{II}$)
- Failure of fastener (tensile fracture of pin, normally not to be expected)

The different failure modes have to be checked. Failure of fastener occurs, as far as relevant during pull-through or pull-out tests. The lowest test result is relevant for determination of tension resistant of the connection.

2.2.1.1 Static pull-through tests

At least 10 pull-through-tests shall be carried out for each relevant sheeting thickness $t_i$. The test load shall be increased until pull-through of the fastener. The respective failure modes as well as the material properties of the sheeting, the base material/steel member and the fastener used for the tests shall be documented in the test report. Furthermore the failure loads shall be given in the test report. The material properties should be documented by means of inspection documents 3.1 according to EN 10204. The material properties have to correspond to the material specifications supplied by the manufacturer. An example for the test setup is shown in Annex 4. The connection to be tested is the connection "Type a" according to Annex 2.

The tensile strength of the material of the component with the thickness $t_i$ (sheeting) should be at the lower limit according to the relevant product standard (e.g. EN 10346). The tensile strength as well as the thickness of the material of the component with the thickness $t_{II}$ (base material, steel member) is optional as long as failure of the base material is excluded.

2.2.1.2 Cyclic pull-through tests

Cyclic pull-through tests are additional optional tests. If they are carried out the following applies: At least 5 cyclic pull-through-tests with a constant amplitude loading range from zero to maximum loading shall be carried out at 3 different load levels for each relevant sheeting thickness $t_i$. The loading frequency should be 5 Hz. The maximum value of each of the 3 different load levels and the corresponding number of cycles until failure as well as the material properties of the sheeting, the base material/steel member and the fastener used for the tests shall be documented in the test report. The material properties should be documented by means of inspection documents 3.1 according to EN 10204. The material properties have to correspond to the material specifications supplied by the manufacturer. An example for the test setup is shown in Annex 4. The connection to be tested is the connection "Type a" according to Annex 2.

The tensile strength of the material of the component with the thickness $t_i$ (sheeting) should be at the lower limit according to the relevant product standard (e.g. EN 10346). The tensile strength as well as the thickness of the material of the component with the thickness $t_{II}$ (base material, steel member) is optional as long as failure of the base material is excluded.

(Remark: According to EN 1993-1-3, Table 8.3, the pull-through resistance may be affected by repeated wind loads. In order to take this into account either calculation according to EN 1993-1-3, Table 8.3, is possible or evaluation of results of static and cyclic pull-through tests.)

2.2.1.3 Pull-out tests

These tests are necessary in combination with all types of fastening tools to be approved for setting the cartridge fired pins. The right setting of the cartridge fired pin is essential for a correct load-bearing connection.

At least 10 pull-out-tests shall be carried out for each relevant base material/steel member thickness $t_{II}$. The test load shall be increased until pull-out or fracture of the fastener. The respective failure modes as well as the material properties of the sheeting, the base material/steel member and the fastener used for the tests shall be documented in the test report. Furthermore the failure loads shall be given in the test report. The material properties should be documented by means of inspection documents 3.1 according to EN 10204. The material properties have to correspond to the material specifications supplied by the manufacturer. An example for the test setup is shown in Annex 5. The connection to be tested is the connection "Type d" or "Type a" with the maximum height of fixture according to Annex 2.

The tensile strength of the material of the component with the thickness $t_i$ (sheeting) is optional. It should be a typical value according to the relevant product standard (e.g. EN 10346). The maximum possible thickness of the sheeting ($4 \times t$) shall be used. This is the maximum thickness for sheeting fastenings where longitudinal and transverse lap joints coincide (side lap and end overlap connection; connection "Type d" according to Annex 2).
The tensile strength of the material of the component with the thickness \( t_{\text{II}} \) (base material, steel member) should be at the lower limit according to the relevant product standard (e.g. appropriate part of EN 10025).

### 2.2.1.4 General handling of the results

The test results of the tests according to 2.2.1.1, 2.2.1.2 and 2.2.1.3 (failure loads / relevant maximum loads / number of cycles until failure as far as relevant) shall be multiplied by the following correction factor which depends on the failure mode:

#### Tests according to Static or Cyclic pull-through tests:

- Failure of sheeting: \( \alpha = \left( \frac{R_{m,\text{min}}}{R_m} \right) \cdot \left( \frac{t_{\text{II},\text{min}}}{t_{\text{II}}} \right) \leq 1.0 \)
- Failure of fastener: \( \alpha = 1.0 \)

#### Tests according to Pull-out tests:

- Pull out failure (structural component \( t_{\text{II}} \)): \( \alpha = 1.0 \)
- Failure of fastener: \( \alpha = 1.0 \)

With:

- \( R_{m,\text{min}} \): minimum tensile strength of the relevant structural components \( t_{\text{I}} \) or \( t_{\text{II}} \) according to the relevant product standard
- \( R_m \): tensile strength of the relevant components \( t_{\text{I}} \) or \( t_{\text{II}} \) used for the tests
- \( t_{\text{I},\text{min}}, t_{\text{II},\text{min}} \): minimum thickness of the relevant structural components \( t_{\text{I}} \) or \( t_{\text{II}} \) according to the relevant product standard (*)
- \( t_{\text{I}}, t_{\text{II}} \): thickness of the relevant components \( t_{\text{I}} \) or \( t_{\text{II}} \) used for the tests (*)

(*) if the component is coated or galvanised the core thickness shall be taken

The corrected test results shall be evaluated statistically according to EN 1990, Annex D.7.2 (determination of 5% fractile, confidence level 75%). Generally a normal distribution can be assumed. The corrected and statistically evaluated test results are the characteristic values of resistance \( N_{R,k} \).

The statistical evaluation of the results of the additional optional cyclic pull-through tests according to 2.2.1.2 refers to the number of cycles until failure. On the basis of the 5% fractile curve of the number of cycles until failure at a certain load level, which shall be determined from the results of tests on 3 different load levels, the pull-through resistance corresponding to 5000 cycles shall be determined. The result is the characteristic value of the pull-through resistance for repeated wind loads. (Remark: Background information is given in the European Convention for Constructional Steelwork ECCS TC7 TWG 7.10 “Connections in Cold-formed Steel Structures”; 2nd Edition, 2009)

Interpolation and extrapolation of characteristic values determined from test results according to 2.2.1.1 and 2.2.1.2 is possible if:

- the difference in thickness of \( t_{\text{I}} \) corresponding to the interpolated characteristic values is \( \leq 0.25 \text{ mm} \) and
- failure of the fastener itself does not occur.

### 2.2.1.5 Characteristic pull-through resistance

The static characteristic pull-through resistance as well as the characteristic pull-through resistance for repeated wind loads shall be determined according to 2.2.1.1.

### 2.2.1.6 Characteristic pull-out resistance

In the ETA the pull-out resistance will be stated only depending on the thickness \( t_{\text{I}} \) (see Annex 8). The only condition for the base material/steel member thickness is: \( t_{\text{II}} \geq 3 \text{ mm} \). Thus the minimum value of all characteristic values of the pull-out resistance determined according to 2.2.1.3 is the relevant characteristic pull-out resistance.
2.2.1.7  Characteristic tension resistance $N_{R,k}$

The characteristic tension resistance is the minimum value of the characteristic values of either pull-through resistance or relevant pull-out resistance for the corresponding connection.

2.2.1.8  Determination of design values of tension resistance $N_{R,d}$

The values for the partial safety factor $\gamma_M$ given in the following are recommended values. They should be used in cases in which no values are given in national regulations of the member state in which the fastener is used or in the respective National Annex to Eurocode 3.

**Design pull-through resistance**

The design value of the static pull-through resistance is the characteristic value of the static pull-through resistance according to 2.2.1.5 divided by the recommended partial safety factor $\gamma_M = 1.25$.

The design value of the pull-through resistance for repeated wind loads should be determined as follows:

- If no cyclic pull-through tests were carried out according to 2.2.1.2, the design rules according to EN 1993-1-3, Table 8.3 should be taken into account. Thus the design value is the design value of the static pull-through resistance multiplied by the reduction factor $\alpha_{\text{cycl}} = 0.5$.

- If cyclic pull-through tests were carried out according to 2.2.1.2, the design value is the design value of the static pull-through resistance multiplied by the following reduction factor $\alpha_{\text{cycl}}$:

  $$\alpha_{\text{cycl}} = 1.5 \times \frac{\text{char. cyclic pull-through resistance}}{\text{char. static pull-through resistance}} \leq 1.0$$

  (Remark: The factor 1.5 takes into account the different safety levels for fatigue design and design for predominantly static loads. $\alpha_{\text{cycl}}$ is limited to 1.0.)

The possibly required reduction of the pull-through resistance due to the position of the fastener shall be taken into account according to EN 1993-1-3, section 8.3 (7) and Fig. 8.2.

**Design pull-out resistance**

The design value of the pull-out resistance is the characteristic value according to 2.2.1.6 divided by the recommended partial safety factor $\gamma_M = 1.25$.

2.2.2  Shear resistance of connection

2.2.2.1  Single layer shear tests

At least 10 shear tests with single sheet layers shall be carried out for each relevant sheeting thickness $t_I$. The test load shall be increased until shear failure of the fastener or local bearing deformation (hole elongation) of the sheeting. The deformation capacity up to maximum load shall be at least 0.5 mm. The maximum load which shall be taken into account in order to determine the relevant characteristic resistance is the maximum load which corresponds to a deformation capacity within a range from 0.5 mm – 3.0 mm. The load-deformation curves and the respective failure modes as well as the material properties of the sheeting, the base material/steel member and the fastener used for the tests shall be documented in the test report. Furthermore the failure loads shall be given in the test report. The material properties should be documented by means of inspection documents 3.1 according to EN 10204. The material properties have to correspond to the material specifications supplied by the manufacturer. An example for the test setup is shown in Annex 6. The connection to be tested is the connection “Type a” according to Annex 2.

The tensile strength of the material of the component with the thickness $t_I$ (sheeting) should be at the lower limit according to the relevant product standard (e.g. EN 10346). The tensile strength as well as the thickness of the material of the component with the thickness $t_{II}$ (base material, steel member) is optional as long as failure of the base material is excluded.

2.2.2.2  Four layer shear tests

At least 10 shear tests with 4 sheet layers shall be carried out for each relevant base material/steel member thickness $t_{II}$. The test load shall be increased until shear failure of the fastener or local bearing deformation (hole elongation) of the sheeting or steel member. The deformation capacity up to maximum load shall be
at least 0.5 mm. The maximum load which shall be taken into account in order to determine the relevant characteristic resistance is the maximum load which corresponds to a deformation capacity within a range from 0.5 mm – 3.0 mm. The load-deformation curves and the respective failure modes as well as the material properties of the sheeting, the base material/steel member and the fastener used for the tests shall be documented in the test report. Furthermore the failure loads shall be given in the test report. The material properties should be documented by means of inspection documents 3.1 according to EN 10204. The material properties have to correspond to the material specifications supplied by the manufacturer. An example for the test setup is shown in Annex 6. The connection to be tested is the connection "Type d" according to Annex 2.

The tensile strength of the material of the component with the thickness $t_i$ (sheeting) should be at the upper limit range according to the relevant product standard (e.g. EN 10346). The maximum possible thickness of the sheeting (4 x $t_i$) shall be used. This is the maximum thickness for sheeting fastenings where longitudinal and transverse lap joints coincide (side lap and end overlap connection; connection "Type d" according to Annex 2).

The tensile strength of the material of the component with the minimum thickness $t_{II}$ (base material, steel member) should be at the lower limit according to the relevant product standard (e.g. appropriate part of EN 10025). The tensile strength of the material of the component with the maximum thickness $t_{II}$ (base material, steel member) should be at the upper range of the application limit according to 2.2.5.

2.2.2.3 Single layer shear test (base material and fastener failure)

In case the intended use of the cartridge fired pin is limited to single layer fastenings these tests have to be executed instead of four layer shear tests. Test execution according to 2.2.2.1

The tensile strength of the material of the component with the thickness $t_i$ (sheeting) should be at the upper limit range of the relevant product standard (e.g. EN 10346). The maximum possible single layer thickness (max $t_i$) shall be used. The tensile strength of the component with the thickness $t_{II}$ (base material, steel member) should be at the lower limit according to the relevant product standard (e.g. appropriate part of EN 10025). The minimum possible base material thickness (min $t_{II}$) shall be used.

2.2.2.4 General handling of the results

The results of the tests according to 2.2.2.1, 2.2.2.2 and 2.2.2.3 (failure loads or maximum loads) shall be multiplied by the following correction factor which depends on the failure mode:

- Local bearing of sheeting: $\alpha = \left( \frac{R_{m,\min}}{R_m} \right) \cdot \left( \frac{t_{i,\min}}{t_i} \right) \leq 1.0$
- Local bearing of metal supporting structure: $\alpha = \left( \frac{R_{m,\min}}{R_m} \right) \cdot \left( \frac{t_{II,\min}}{t_{II}} \right) \leq 1.0$
- Failure of fastener: $\alpha = 1.0$

With:

$R_{m,\min} =$ minimum tensile strength of the relevant structural components $t_i$ or $t_{II}$ according to the relevant product standard

$R_m =$ tensile strength of the relevant components $t_i$ or $t_{II}$ used for the tests

$t_{i,\min}$, $t_{II,\min} =$ minimum thickness of the relevant structural components $t_i$ or $t_{II}$ according to the relevant product standard *)

$t_i$, $t_{II} =$ thickness of the relevant components $t_i$ or $t_{II}$ used for the tests *)

*) if the component is coated or galvanised the core thickness shall be taken

The corrected test results shall be evaluated statistically according to EN 1990, Annex D.7.2 (determination of 5% fractile, confidence level 75%). Generally a normal distribution can be assumed. The corrected and statistically evaluated test results are the characteristic values of resistance.

2.2.2.5 Characteristic shear resistance $V_{R,k}$

The characteristic shear resistance is the minimum value of the characteristic values determined according to 2.2.2.4 for the corresponding connection.

©EOTA 2015
2.2.2.6 Determination of design values of shear resistance $V_{R,d}$

The value for the partial safety factor $\gamma_M$ given in the following is a recommended value. It should be used in cases in which no value is given in national regulations of the member state in which the fastener is used or in the respective National Annex to Eurocode 3.

The design value of the shear resistance is the characteristic value according to 2.2.2.5 divided by the recommended partial safety factor $\gamma_M = 1.25$. 

2.2.3 Design resistance in case of combined tension and shear forces (interaction)

In case of combined tension and shear forces the following linear interaction formula should be taken into account (see also EN 1993-1-3, formula (8.2)).

$$\frac{V}{V_{R,d}} + \frac{N}{N_{R,d}} \leq 1.0$$

With:

$V =$ design value of acting shear load

$N =$ design value of acting tensile load

2.2.4 Check of deformation capacity in case of constraining forces due to temperature

In order to check the sufficient deformation capacity in case of constraining forces due to temperature at least 10 shear / pull-out tests with 2 sheet layers shall be carried out for the minimum base material/steel member thickness $t_1 (\geq 3 \text{ mm})$ and the maximum base material/steel member thickness $t_2$ (but not more than 20 mm). The test load shall be increased up to a lateral deformation of 2 mm. After the lateral deformation the remaining pull-out resistance of the fastener shall be determined. The material properties of the sheeting, the base material/steel member and the fastener used for the tests shall be documented in the test report. Furthermore the failure loads shall be given in the test report. The material properties should be documented by means of inspection documents 3.1 according to EN 10204. The material properties have to correspond to the material specifications supplied by the manufacturer.

The connection "Type b" is the most unfavourable connection concerning constraining forces (lateral forces) due to temperature. Thus the connection to be tested is the connection "Type b" (see Annex 2). An example for the test setup is shown in Annex 7.

The tensile strength of the material of the component with the thickness $t_1$ (sheeting) should be at the upper limit range according to the relevant product standard (e.g. EN 10346). The thickness of the sheeting (2 x $t_1$) is the maximum thickness for sheeting fastenings for longitudinal joints (side lap connections). The tensile strength of the material of the component with the minimum thickness $t_2$ (base material, steel member) should be at the lower limit according to the relevant product standard (e.g. appropriate part of EN 10025). The tensile strength of the material of the component with the maximum thickness $t_2$ (base material, steel member) should be at the upper range of the application limit according to 2.2.5.

No shear failure may occur up to the deformation of 2 mm. The remaining pull-out resistance of each fastener shall be at least 50% of the minimum pull-out resistance according to 2.2.1.6 (Remark: Due to the intended use constraining forces due to temperature may only occur during the construction stage.) In case the intended use of the cartridge fired pins is limited to single layer fastenings, the check of the deformation capacity has to be executed with the maximum single layer thickness (max $t_1$) instead with the maximum double layer thickness (2 x $t_1$).

2.2.5 Determination and check of application limits

These tests are necessary in combination with all types of fastening tools to be approved for setting the cartridge fired pins.
The application limits, such as minimum and maximum penetration depth, maximum strength of base material depending on the corresponding thickness \( t_{II} \), type of fastening tool and cartridge as well as maximum nail head standoff (see Annex 8) shall be determined by the manufacturer. The application limits concerning the maximum strength of the base material depending on the corresponding thickness \( t_{II} \) (see Annex 8) shall be checked by pull-out tests according to 2.2.1.3. The tensile strength of the material of the component with the thickness \( t_I \) (sheeting) is optional. It should be a typical value according to the relevant product standard (e.g. EN 10346). The minimum possible thickness \((1 \times t_I)\) as well as the maximum possible thickness \((4 \times t_I)\) of the sheeting shall be used. The tensile strength of the material of the component with the thickness \( t_{II} \) (base material, steel member) shall be at the upper application limit according to the application diagram (see Annex 8) determined by the manufacturer. The pull-out resistance shall be at least the minimum resistance determined according to 2.2.1.6.

2.2.6 Reaction to fire

The cartridge fired pin is considered to satisfy the requirements to performance class A1 of the characteristic reaction to fire, in accordance with the provisions of EC decision 96/603/EC (as amended) without the need for testing on the basis of conformity with the specification of the product detailed in that Decision and its intended end use application being covered by that Decision. The product shall be classified according to EN 13501-1.

2.2.7 Resistance to fire

The part of the works or assembled system in which the cartridge fired pins are intended to be incorporated, installed or applied shall be tested, using the test method relevant for the corresponding fire resistance class, in order to be classified according to the appropriate part of EN 13501.

2.2.8 Content, emission and/or release of dangerous substances

The performance of the product related to the emissions and/or release and, where appropriate, the content of dangerous substances will be assessed on the basis of the information provided by the manufacturer using the following methods and criteria: EOTA TR 034, in particular for

- “T+” or “T”, Carcinogenic (T, R 45; T, R 49) and mutagenic (T, R 46) substances of categories 1 and 2 respectively 1A and 1B (CLP): EOTA TR 034, Substance list, No 1;
- VOC, SVOC: EOTA TR 034, Substance list, No 7;

based on the distinction made between the following areas of application:

IA2: Product with no direct contact to (e.g. covered products) but possible impact on indoor air,
S/W2: Product with no direct contact to but possible impact on soil-, ground- and surface water.

2.2.9 Durability

For the corrosion protection of the cartridge fired pins and therewith executed connections the rules given in EN 1993-1-3 and EN 1090-2 shall be taken into account. Cartridge fired pins which are intended to be used in external environments according to the standard EN ISO 12944-2:1998 shall be protected properly against the influence of corrosive media.

3 ASSESSMENT AND VERIFICATION OF CONSTANCY OF PERFORMANCE

3.1 System of assessment and verification of constancy of performance to be applied

For the products covered by this EAD the applicable European legal act is: Decision 1998/214/EC, amended by 2001/596/EC

©EOTA 2015
The system is: 2+

3.2 Tasks of the manufacturer

The corner stones of the actions to be undertaken by the manufacturer of the cartridge fired pin in the procedure of assessment and verification of constancy of performance are laid down in Table 2.

Pull-through specimen (with or without folded lip)

Test setup for pull-through tests
Pull-out test with pull-through specimen

Test setup according to Annex 4

Pull-out test with nail head adapter set
Shear test setup

Single layer shear test

Four layer shear test

Remark: Clamping of the specimen in the test equipment has to be done in such a way, that the axis of the load is lying in the interface between the sheeting ($t_1$) and the base material ($t_{II}$).
Test set-up and procedure for shear / pull-out test

Procedure:
Step 1: Increase of shear load up to a lateral deformation of 2 mm
Step 2: Pull-out of the fastener (either with pull-through specimen or with direct pulling of the fastener head according to Annex 5)
